Abstract: This paper deals with a designing problem of discrete-time and discrete-value (discretized) control systems based on a model-reference feedback structure. The model used in this study is assumed to be a second-order lag system that is expressed by a bilinear transformation. That type of discretized (nonlinear) control systems is presented and analyzed. The model reference feedback using a second-order continuous-value (linear) system is equivalently transformed into a traditional PID control. The robust stability analysis and design of such nonlinear control systems is examined in a frequency domain. Numerical examples for model-reference type discretized control are provided to verify the design method.

Keywords: Nonlinear systems; robust stability; discretization; quantization; model reference control.

1. INTRODUCTION

Almost all feedback control systems are realized using discretized (discrete-time and discrete-value) signals. However, the analysis and design of discretized/quantized control systems has not been entirely elucidated. An attempt to elucidate the quantized control systems was presented first in a paper (Kalman [1956]). Since then, the problem of mitigating the quantization effects in quantized control systems has been studied (Delchamps [1990], Elia and Mitter [2001], Fu [2003]). However, few results have been obtained for the analysis and design of that type of nonlinear discrete-time control systems (Desoer and Vidyasagar [1975]).

In our previous papers (Okuyama [2006, 2008, 2009]), the robust stabilization of nonlinear discrete-time and discrete-value (discretized) control systems was examined in a frequency domain. In the study, a traditional (discrete-time) PID control scheme was used in the controller design. In the design procedure, the concept of a modified Nyquist and Hall diagram (off-axis M-circles) for nonlinear control systems in (Okuyama et al. [2002a]) is applied.

This paper describes a designing problem of such discretized control systems based on a model-reference feedback structure. The model-reference feedback using a second-order continuous-value (linear) system is equivalently transformed into a traditional PID control. This control scheme is referred to as a quasi-PID control in this paper. The robust stability analysis and design of such nonlinear control systems is examined in a frequency domain.

2. BILINEAR TRANSFORMATION AND MODEL REFERENCE FEEDBACK

Model reference feedback structure for a robust control system was once proposed by the author. A discrete-time version of the model reference feedback was presented in (Takemori and Okuyama [2000]). In this paper, a discretized model reference control system as shown in Fig. 1 is examined. Here, $P(s)$ is a continuous-time and continuous-value plant, and $P(z)$ is the $z$-transform of $P(s)$ together with the zero-order hold $H$. On the other hand, $N(\cdot), D_1$ and $D_2$ are a nonlinear element and the input and output discretizing units which are determined by sensor and actuator elements. In the figure, each symbol $e$, $v$, $\cdots$ indicates the sequence $e(k), v(k), \cdots$ ($k = 0, 1, 2, \cdots$) in discrete time, but for continuous value. On the other hand, each symbol $e^\dagger$, $v^\dagger$, $\cdots$ indicates a discrete value that can be assigned to an integer number, e.g.,

\[ e^\dagger \in \{ \cdots, -2\gamma_1, -\gamma_1, 0, \gamma_1, 2\gamma_1, \cdots \}, \]
\[ v^\dagger \in \{ \cdots, -2\gamma_2, -\gamma_2, 0, \gamma_2, 2\gamma_2, \cdots \}, \]

(1)
where $\gamma_1$ and $\gamma_2$ are the resolution of each variable. The
discretized nonlinear characteristic $v^{\dagger} = N_d(\cdot)$ is depicted
as shown in Fig. 2. The resolutions in $D_1$ and $D_2$ are chosen as
$\gamma_1 = 2.0$ and $\gamma_2 = 1.0$ in this example. $D_1$ and $D_2$ are the
discretizing units in the discrete-time model $KP_m(z)$ and the
feedback compensator $F(z)$. Those resolutions are considered
$\gamma_1 = \gamma_2 = \gamma_2/n$. Thus, when $n \to \infty$, the controller part can
be considered a linear continuous system.

In this study, the model system, $KP_m(z)$ ($K$: nominal linear gain
of $N_d(\cdot)$), is assumed to be a second-order lag system, e.g.,
\begin{equation}
KP_m(z) = K \hat{P}_m(\delta) = \frac{K}{1 + C_1 \delta + C_2 \delta^2}.
\end{equation}

where $\delta$ is the following bilinear transformation:
\begin{equation}
\delta = \frac{2}{h} \frac{z - 1}{z + 1} \quad (h: \text{ sampling period}).
\end{equation}

Here, $C_1$ and $C_2$ are the design parameters of the model system.

The $z$-transform expression of (2) is given by
\begin{equation}
KP_m(z) = \frac{K h^2 (z + 1)^2 + 2 C_1 h (z + 1)(z - 1) + 4 C_2 (z - 1)^2}{K (h^2 (z + 1)^2 + 4 C_2 (z - 1)^2)}.
\end{equation}

Obviously, $\delta$ approaches Laplace transform variable $s$, when
the sampling period is $h \to 0$.

The operator $\delta$ has the following properties:

1. Since $\delta^{-1} = \frac{h}{2} \frac{1 + z^{-1}}{1 - z^{-1}}$, the relationship between the
input and output sequences, $y(k), y(k)$, $(k = 0, 1, 2, \cdots)$
can be written as:
\begin{equation}
y(k) = y(k - 1) + \frac{h}{2} (x(k) - x(k - 1)).
\end{equation}

2. On the other hand, with respect to the operator $\delta$, the
following relation can be obtained:
\begin{equation}
y(k) = -y(k - 1) + \frac{2}{h} (x(k) - x(k - 1)).
\end{equation}

In this paper, $\delta$ will be used instead of $z$-transform operator.
Therefore, the feedback compensator $F(z)$ as shown in Fig. 1
is defined as:
\begin{equation}
F(z) = \tilde{F}(\delta) = \frac{1 + C_1 \delta + C_2 \delta^2}{K (1 + C_1 \delta + C_2 \delta^2)}.
\end{equation}

Here, $C_1$ and $C_2$ are the design parameters of the feedback
compensator. Thus, the $z$-transform expression of (7) is written as:

\begin{equation}
F(z) = \frac{h^2 (z + 1)^2 + 2 C_1 h (z + 1)(z - 1) + 4 C_2 (z - 1)^2}{K (h^2 (z + 1)^2 + 4 C_2 (z - 1)^2)}.
\end{equation}

In the frequency domain, $\delta$ can be expressed as:
\begin{equation}
\delta(e^{j\omega}) = j \Omega (\omega) = j \frac{2}{h} \tan \left( \frac{\omega h}{2} \right), \quad j = \sqrt{-1},
\end{equation}

where $\Omega$ is a distorted frequency of $\omega$. Using this expression,
(2) and (7) can be written as follows:
\begin{equation}
KP_m(e^{j\omega}) = \hat{P}_m(j \Omega) = \frac{K}{1 - C_2 \Omega^2 + j C_1 \Omega},
\end{equation}

and
\begin{equation}
F(e^{j\omega}) = \tilde{F}(j \Omega) = \frac{1 - C_2 \Omega^2 + j C_1 \Omega}{K (1 - C_2 \Omega^2 + j C_1 \Omega)}.
\end{equation}

The block diagram of model-reference control systems can be
redrawn as shown in Fig. 5.

3. QUASI-PID CONTROL AND ITS IMPROVEMENT

When controllers are in high resolution, i.e., $n \to \infty$, the
model-reference control system as shown in Fig. 1 can be transformed
into Fig. 4. Here, $\nu$ is a disturbance signal generated by the
discretization of controllers. The equivalent controller $C(z)$
and the pre-compensator $D(z)$ are given by

\begin{equation}
C(z) = \tilde{C}(\delta) = \frac{1 + C_1 \delta + C_2 \delta^2}{c_1 \delta + c_2 \delta^2},
\end{equation}

\begin{equation}
D(z) = \tilde{D}(\delta) = \frac{1 + C_1 \delta + C_2 \delta^2}{1 + C_1 \delta + C_2 \delta^2}.
\end{equation}

Here, $C(z)$ can be considered to be a controller when $c_2 \ll c_1$.
If $c_2 \to 0$, the controller is approximately written as:

\begin{equation}
\tilde{C}(\delta) = \frac{c_1 \delta^{-1} + C_1}{c_1 + C_2 \delta}.
\end{equation}

When the sampling period is $h \to 0$, $\delta$ becomes Laplace
transform variable $s$. Therefore, the scheme will correspond to
a traditional continuous PID control.

The $z$-tranform of (14) is given by
\begin{equation}
C(z) = \frac{h}{2 c_1} \frac{z + 1}{z - 1} + \frac{C_1}{c_1} \frac{2 C_2}{c_1 h}. \frac{z - 1}{z + 1}.
\end{equation}

In the distorted frequency domain, it can be expressed as
\begin{equation}
\tilde{C}(j \Omega) = \frac{C_1}{c_1} + j \frac{1}{c_1} \left( C_2 \Omega - \frac{1}{\Omega} \right).
\end{equation}

These algorithms (12) and (15) are referred to as quasi-PID
control in this paper.

With respect to higher-order and time-delay plants, the model
system $KP_m(z)$ can be improved by
\begin{equation}
KP_m(\delta) = \frac{K}{1 + C_1 \delta + C_2 \delta^2} \cdot e^{-L_m s},
\end{equation}
where \( L_m \) is the inserted time-delay of the model system. Since the feedback compensator that has a time-lead characteristic cannot be realized, the quasi-PID controller should be written as:
\[
\tilde{C}(\delta) = \frac{1 + C_1 \delta + C_2 \delta^2}{K(1 + c_1 \delta + c_2 \delta^2)} - z^{-d_m}, \quad d_m = L_m / h. \tag{18}
\]

4. SUM OF TRAPEZOIDAL AREAS

The discretized nonlinear characteristics as shown in Fig. 2 is partitioned as follows:
\[
v^i = N_i(e^i(k)) = ke^i + g(e^i), \quad 0 < K < \infty, \tag{19}
\]
\[
|w^i| = |g(e^i)| \leq \bar{g} < \infty, \quad \text{for} \quad |e^i| < \varepsilon, \tag{20}
\]
\[
|w^i| = |g(e^i)| \leq \beta |e^i|, \quad \text{for} \quad |e^i| \geq \varepsilon. \tag{21}
\]
in regard to \( e^i \in e \). Therefore, when analyzing the robust stability in a global sense, it is sufficient to consider the nonlinear term (21), because the nonlinear term (20) can be treated as a disturbance signal. In this study, since the nonlinear characteristic (19) is assumed to exist in the first and the third quadrant, the sector parameter \( \beta \) should be considered in the following range:
\[
0 \leq \beta \leq K. \tag{22}
\]

The robust stability of discretized systems as shown in Fig. 4 is analyzed based on the inner-product and norm analysis in the \( \ell_2 \) space. In regard to (21), the following new nonlinear function can be defined:
\[
f(e) := g(e) + \beta \cdot e. \tag{23}
\]

When considering the discretized output of the nonlinear characteristic, \( w^i = g(e^i) \), the following expression is given:
\[
f(e^i(k)) = w^i(k) + \beta \cdot e^i(k). \tag{24}
\]

From inequality (21), it can be seen that the function (24) belongs to the first and third quadrants.

For the neutral points of \( e^i(k) \) and \( w^i(k) \), the following expression is given from (24):
\[
\frac{1}{2}(f(e^i(k)) + f(e^i(k - 1))) = w^i_m(k) + \beta e^i_m(k), \tag{25}
\]
where
\[
w^i_m(k) = \frac{w^i(k) + w^i(k - 1)}{2}, \quad e^i_m(k) = \frac{e^i(k) + e^i(k - 1)}{2},
\]
The trapezoidal area of one-step transition on the grid pattern \( f(e) \) is, therefore, written as follows:
\[
\tau(k) := \frac{1}{2}(f(e^i(k)) + f(e^i(k - 1))) \Delta e^i(k)
\]
\[
= (w^i_m(k) + \beta e^i_m(k)) \Delta e^i(k). \tag{26}
\]

Here, \( \Delta e^i(k) \) is the backward difference of sequence \( e^i(k) \).
\[
\Delta e^i(k) = e^i(k) - e^i(k - 1).
\]

Since \( f(e^i(k)) \) belongs to the first and third quadrants, the area of each trapezoid \( \tau(k) \) is non-negative when \( e(k) \) increases (decreases) in the first (third) quadrant. On the other hand, the trapezoidal area \( \tau(k) \) is non-positive when \( e(k) \) decreases (increases) in the first (third) quadrant.

In our study, the following assumption is provided with respect to the discretized response on a grid pattern.

**Assumption.** The absolute value of the backward difference of sequence \( e(k) \) does not exceed \( \gamma \), i.e.,
\[
|\Delta e(k)| = |e(k) - e(k - 1)| \leq \gamma. \tag{27}
\]

\[\text{Fig. 5. Nonlinear subsystem.}\]

\[\text{Fig. 6. Equivalent feedback system.}\]

If condition (27) is satisfied, \( \Delta e^i(k) \) is exactly \( \pm \gamma \) or 0 because of the discretization. That is, the absolute value of the backward difference can be given as
\[
|\Delta e^i(k)| = |e^i(k) - e^i(k - 1)| = \gamma \text{ or 0.} \tag{28}
\]

This assumption will be satisfied in the following examples.

Consider the following sum of trapezoidal areas:
\[
\sigma(p) := \sum_{k=1}^{p} \tau(k). \tag{29}
\]

If the above assumption is satisfied with respect to the discretization of the control system, the sum of trapezoidal areas, \( \sigma(p) \), becomes non-negative for any \( p \). Since the discretized output traces the same points on the stepwise nonlinear characteristic, the sum of trapezoidal areas is canceled when \( e(k) \) (and \( e^i(k) \)) decreases (increases) from a certain point \( (e^i(k), f(e^i(k))) \) in the first (third) quadrant. (Here, without loss of generality, the response of discretized point \( (e^i(k), f(e^i(k))) \) is assumed to commence at the origin.)

From equation (26), the sum of trapezoidal areas can be expressed as follows:
\[
\sigma(p) := \frac{1}{2} \sum_{k=1}^{p} (f(e^i(k)) + f(e^i(k - 1))) \Delta e^i(k)
\]
\[
= \langle w^i_m(k) + \beta e^i_m(k), \Delta e^i(k) \rangle_p. \tag{30}
\]

Here, \( \langle \cdot, \cdot \rangle_p \) denotes the inner product in the \( \ell_2 \) space,
\[
\langle x_1(k), x_2(k) \rangle_p = \sum_{k=1}^{p} x_1(k)x_2(k).
\]

5. ROBUST STABILITY IN A GLOBAL SENSE

In order to derive the robust condition, the following new sequences are considered here:
\[
e^i_m(k) = e^i_m(k) + q \cdot \frac{\Delta e^i(k)}{h}, \tag{30}
\]
\[
w^i_m(k) = w^i_m(k) - \beta \cdot \frac{\Delta e^i(k)}{h}. \tag{31}
\]

where \( q \) is a non-negative number. The relationship between equations (30) and (31) is as shown in Fig. 5. Based on these
sequences, the following lemma is given (Okuyama et al. [1999]):
Lemma 1. If the following inequality is satisfied with respect to
the inner product of the neutral points of (24) and the backward
difference:
\[ \langle w_m^t(k) + \beta e_m^t(k), \Delta e^t(k) \rangle_p \geq 0, \] (32)
the following inequality can be obtained:
\[ \| w_m^t(k) \|_{2,p} \leq \beta \| e_m^t(k) \|_{2,p} \] (33)
for any \( q \geq 0 \). Here, \( \| \cdot \|_{2,p} \) denotes the Euclidean norm, which
can be defined by
\[ \| x(k) \|_{2,p} := \left( \sum_{k=1}^{p} x^2(k) \right)^{1/2}. \]

Proof. The proof is given in (e.g., Okuyama [2006]). \( \square \)

By applying a small gain theorem to the loop transfer charac-
teristic, the following robust stability condition for discretized
nonlinear control systems can be derived (Okuyama [2008]).

Theorem 2. If there exists a \( q \geq 0 \) in which the parameter \( \beta \)
with respect to nonlinear term \( g(\cdot) \) satisfies the following
inequality, the discrete-time control system with sector nonlin-
earity (21) is robust stable in an \( \ell_2 \) sense:
\[ \beta < \beta_0 = K \cdot \eta(q_0, \omega_0) = \max_{q \geq 0} \min_{\omega \geq \omega_0} K \cdot \eta(q, \omega), \] (34)
where the linearized system with nominal gain \( K \) is stable. That
is, the allowable sector can be given as \( [0, \beta_0] \) from (34). Here, \( \omega_c \)
is a cut-off frequency that is defined based on the sampling
theorem. The \( \eta \)-function is written as follows:
\[ \eta(q, \omega) := -q \Omega V + \sqrt{q^2 \Omega^2 V^2 + (U^2 + V^2)((1 + U^2)^2 + V^2)} \]
(35)
where \( U(\omega) \) and \( V(\omega) \) are the real and the imaginary parts
of the loop transfer function \( K P(e^{j\omega c}) C(e^{j\omega c}) \).

Proof. The loop transfer function from \( w^* \) to \( e^* \) can be given by \( W(\beta, q, \delta) \) as shown in Fig. 6, where
\[ W(\beta, q, \delta) = \frac{(1 + q \delta) P(\delta) C(\delta)}{1 + (K + \beta \delta) P(\delta) C(\delta)}, \] (36)
and \( r^*, d^* \) are transformed exogenous inputs. Here, the variables
such as \( e^*, w^*, u^* \) and \( y^* \) written in Fig. 6 indicate the \( \delta \)-
transformed ones.

Based on the loop characteristic in Fig. 6, the following inequality
can be given with respect to \( \delta = j\Omega \):
\[ \| e_m^t(\delta) \|_{2,p} \leq k_1 \| r_m^t(\delta) \|_{2,p} + k_2 \| d_m^t(\delta) \|_{2,p} \]
\[ + \sup_{\delta = j\Omega} \| W(\beta, q, \delta) \| \| e_m^t(\delta) \|_{2,p}. \] (37)
Here, \( r_m^t(\delta) \) and \( d_m^t(\delta) \) denote the \( \delta \)-transformation for the
neutral points of sequences \( r(k) \) and \( d(k) \), respectively. More-
over, \( k_1 \) and \( k_2 \) are positive constants.

By applying the result of Lemma 1, the following expression
can be obtained:
\[ \left( 1 - \beta \cdot \sup_{\delta = j\Omega} \| W(\beta, q, \delta) \| \right) \| e_m^t(\delta) \|_{2,p} \]
\[ \leq k_1 \| r_m^t(\delta) \|_{2,p} + k_2 \| d_m^t(\delta) \|_{2,p}. \] (38)
Therefore, if the following inequality is valid,
\[ |W(\beta, q, \delta)| = \left| \frac{(1 + q\delta \Omega(\omega)) (U(\omega) + j V(\omega))}{K + (K + j\beta \delta \Omega(\omega)) (U(\omega) + j V(\omega))} \right| < \frac{1}{\beta}. \] (39)
the sequences \( e_m^t(k) \), \( e_m^t(k) \), \( e(k) \) and \( y(k) \) are restricted in
finite values, when exogenous inputs \( r(k) \) and \( d(k) \) are finite and \( p \rightarrow \infty \). From the square of both sides of inequality (39), the
result of theorem is given. \( \square \)

6. NYQUIST CURVE AND OFF-AXIS M-CIRCLES

The design method is based on a Nyquist curve and off-axis
M-circles. In the previous papers (Okuyama et al. [2002a,b]), the
inverse function was used instead of the \( \eta \)-function, i.e.,
\[ \xi(q, \omega) = \frac{1}{\eta(q, \omega)}. \] Using this notation, inequality (34) can be
rewritten as follows:
\[ M_0 = \min_{q \geq 0} \max_{\omega \geq \omega_0} K \cdot \eta(q, \omega) \] (40)
When \( q = 0 \), the \( \xi \)-function can be expressed as:
\[ \xi_0(\omega) = \frac{1}{\eta_0(\omega)} = |S_0(e^{j\omega c})|, \] (41)
where \( S_0(z) \) is the complementary sensitivity function for the
discrete-time system.

It is evident that the following curve on the complex plane,
\[ \xi(0, \omega) = M, \] (M : const.) (42)
corresponds to an M-circle in the Hall diagram. In this study, since
an arbitrary non-negative number \( q \) is considered, the \( \xi \)-
function that corresponds to (41) and (42) is given as follows:
\[ \frac{-q \Omega V + \sqrt{q^2 \Omega^2 V^2 + (U^2 + V^2)((1 + U^2)^2 + V^2)}}{U^2 + V^2} = M. \] (43)
From this expression, the following quadratic equation can be
obtained:
\[ (M^2 - 1)U^2 + 2M^2 U + (M^2 - 1)V^2 + M^2 - 2Mq \Omega V = 0. \] (44)
When \( M > 1 \), the following is obtained from (44).
\[ \left( \frac{U + M^2}{M^2 - 1} \right)^2 + (V - M)^2 = \frac{M^2}{(M^2 - 1)^2} + \lambda^2, \]
\[ \lambda = q \Omega M/(M^2 - 1) \geq 0. \] (45)
Although the distorted frequency \( \Omega \) is a function of \( \omega \), the term
\( q \Omega = q_0 \geq 0 \) is assumed to be a constant parameter in
this paper. Thus, it can been seen that (45) represents off-axis circles
with their center at \(-M^2/(M^2 - 1), \lambda \) and with radius of
\sqrt{M^2/M^2 - 1} + \lambda^2.

Figure 7 shows an example of the modified Hall diagram and
Nyquist curves of a control system with time delay. Here, \( N_1 \)
is a vector locus that contacts with an M-circle at the peak value
\( M_0 = \xi(0, \omega_0) = 1.4 \). On the other hand, \( N_2 \) is a vector locus
that contacts with a circle C on the real axis, where all the M-
circles cross the real axis. The latter case corresponds to the
discrete-time system in which Aizerman’s conjecture is valid
(Okuyama et al. [1998]). At the continuous saddle point where
is also the phase-crossover point \( P_c \), the following equation is
satisfied:
\[ \left( \frac{\partial \xi(q, \omega)}{\partial q} \right)_{q=q_0, \omega=\omega_0} = 0. \] (46)
Evidently, the phase margin \( p_M \) is obtained from the gain-
crossover point \( G_c \).
7. NUMERICAL EXAMPLES

Example 1. Consider the following continuous plant:
\[ P(s) = \frac{K_1}{(s + 0.1)(s + 0.2)(s + 0.5)}. \]  
(47)
where the gain constant is \( K_1 = 0.01 \) and the sampling period is \( h = 1.0 \). The discretized nonlinear characteristic considered here (discretized sigmoid, i.e. arc tangent) is as shown in Fig. 2. The resolutions of the input and output sequences of \( N_d(N) \) are chosen as \( \gamma_1 = 2.0 \) and \( \gamma_2 = 1.0 \). When the nominal gain \( K = 1.0 \) and the threshold \( \varepsilon = 2.0 \) are considered, the sectorial area of the stepwise nonlinear characteristic for \( \varepsilon \leq |e| \) can be determined as \([0.5, 1.5]\). In this example, the resolutions of model system \( K_Pm(z) \) and feedback compensator \( F(z) \) are defined as \( \gamma_{c1} = \gamma_{c2} = \gamma_2/25 = 0.04 \).

As for the first case (i), the model system is chosen as follows:
\[ K\hat{P}_m(\delta) = \frac{1}{1 + 8.0\delta + 8.0\delta^2}. \]  
(48)
And the feedback compensator is defined as:
\[ \hat{F}(\delta) = \frac{1 + 8.0\delta + 8.0\delta^2}{1 + 8.0\delta + \delta^2}. \]  
(49)
The step response of (i) is depicted in Fig. 11. On the other hand, as for the second case (ii), the model system and the feedback compensator are the same as (50). The feedback compensator is the same as (49). In this case, the step response of (ii) is well stabilized and designed as shown in Fig. 8.

When the model and compensator are considered in high resolution, the equivalent controller can be written as
\[ \hat{C}(\delta) = \frac{1 + 8.0\delta + 8.0\delta^2}{8.0\delta + \delta^2}. \]  
(51)
Therefore, the Nyquist plots and the off-axis M-circles of these cases is as shown in Fig. 10. (Hereafter, the cut-off frequency is chosen as \( \omega_c = 0.3 \).) The parameter tuning and designing of the above model-reference control systems can be performed in this diagram. In either case, since the sector parameter \( \beta \) becomes not less than \( K = 1.0 \) from (22), it should be considered \( \beta_0 = 1.0 \) (i.e., the allowable sector is regarded as \([0.0, 2.0]\)). Thus, the robust stability of the control system is guaranteed.

Example 2. Consider the following continuous plant with time delay:
\[ P(s) = \frac{K_2}{(s + 0.1)(s + 0.2)(s + 0.5)} e^{-Ls}. \]  
(52)
where \( K_2 = 0.01 \) and \( L = 4.0 \). The resolutions of the model and compensator are the same as in Example 1. In addition, as for the first case (i), the model system and the feedback compensator are the same as (48) and (49), respectively. The step response of (i) is depicted in Fig. 11. On the other hand, as for the second case (ii), the model system and the feedback compensator are the same as (50) and (49). Also in this case, the step response is well stabilized as shown in Fig. 8. When the model system and feedback compensator are in high resolution, the sector parameter becomes \( \varepsilon = 0.0 \). When the model system and feedback compensator are in high resolution, the sector parameter becomes \( \beta_0 = 0.78 \) (i.e., the allowable sector is determined as \([0.22, 1.78]\)). Figure 12 shows the Nyquist plots and the off-axis M-circles of these cases. The parameter tuning and designing of the above model-reference
control systems can be performed in this diagram. Thus, the robust stability of the control system is satisfied in either case of the above.

Example 3. Consider the following continuous plant with time delay:

\[ P(s) = \frac{K_3(s + 0.3)(-s + 0.5)}{(s + 0.1)(s + 0.2)(s + 0.5)} e^{-Ls}, \]  

where \( K_3 = 0.05 \) and \( L = 5.0 \). This is an example of non-minimum phase plants. The resolutions of the model and compensator are the same as in Example 1. As for the first case (i), the model system and the feedback compensator are the same as (48) and (49). The step response of (i) is depicted in Fig. 13. On the other hand, for the second case (ii), the model system and the feedback compensator are the same as (50) and (49). (Here, the time delay of the model system is chosen as \( L_m = 0.5 \). Also in this case, the step response of (ii) is well stabilized as shown in Fig. 13. This is a counter example of Aizerman’s conjecture.

8. CONCLUSION

This paper has described a designing problem of discrete-time and discrete-value (discretized) control systems based on a model reference structure. The robust stability of that type of nonlinear control systems was examined in a frequency domain. The model reference feedback using a second-order continuous-value (linear) system was equivalently transformed into a traditional PID control. Based on the model reference structure, the robust stabilization and design of continuous plants could be achieved. The result of numerical examples show good performances and step responses. In general, the design method will be applied to digital and discrete control systems.
